CHAPTER I

INTRODUCTION

Before proceeding with the main subject of this paper, it is necessary to present some background information on the Army and Air Force Exchange Service (AAFES) of which the Malmstrom Base Exchange is a member.

The primary function of the Base Exchange (BX) is to provide a merchandising service to the military family. The BX was initially established to provide necessities, however, the concept of "necessities" today is a much debated issue between the BX and retail establishments, and is not essential to this paper. Suffice it to say that the BX offers a vast variety of products and services.

In addition to its normal sales outlets, the BX supports such services as theaters, libraries, bowling alleys, cafeterias, and hobby shops, many of which do not generate profits. In order to provide these services the BX must make profits on its merchandising operations. Its means of doing so are limited by its own primary objective of providing a service, and by legislation.

Many profit-generating tactics employed by normal business enterprises are not available to the BX. Prices are set by regulation, not by the management. Powerful civilian lobbying continues to restrict product mix. The BX, for example, is prohibited from selling high priced, high turnover items such as stereo components and cameras. Normal advertising is also prohibited.
The imposition of these restrictions, among others, demands that the BX take full advantage of allowable marketing practices. The major purpose of this study was to determine, through its consumer image, which areas of its marketing mix might be improved.

The decision to make this study resulted from casual conversations with fellow combat crewmembers. One recurring topic of conversation concerned a lack of satisfaction with BX facilities. Whether the problem was stock-outs, inadequate price advantages, lack of variety, bad service, or a myriad of other complaints, the conversation was usually curtly dismissed with, "What's new!" A second purpose of this study was to determine the extent of this dissatisfaction, or more properly, to determine if it were just idle complaining.

A vast amount of research has been undertaken in the consumer behavior area of store image. Previous research has revealed six major criteria with which the consumer forms his image of a store, (1) location, (2) product mix, (3) price, (4) advertising, (5) store personnel, and (6) services offered. ¹ Store selection is then a result of the process of comparing these criteria with the perceived characteristics of the individual store.

As summarized by Engel, et al,² the following general conclusions are presented. Work by Stonier and Johnson revealed that distance and parking convenience were the main reasons people preferred to shop outside of the central city. Alderson and Sessions indicated that a store offering a wide variety or a deep assortment of product lines would be preferred

²Ibid., pp. 452-453.
over those having medium depth or breadth of assortment. Research in the affect of price was inconclusive but Rich and Portis, among others, indicated that it ranked far down on the list of reasons for shopping at a particular store.

The perceived characteristics with which the consumer compared the foregoing criteria fell into the same general categories. The formation of the required images is not described by well-developed theory, however, the following are suggested as major determinants.³

a. Price - the consumer's perceived price may differ from the actual price. Many factors influence this perception, among which are advertisements, displays, specials, etc.

b. Advertising - advertising is quite important, yet it is often misdirected. Without visiting a store, the consumer must rely on advertising to form an image. Class appeal, price, etc., are all reflected in advertising.

c. Product and Service Mix - a store must offer the products and services that a consumer desires in order to create a favorable image.

d. Store Personnel - the consumer will transfer his image of the personnel waiting on him into his image of the entire store.

e. Physical Attributes - quality of construction materials, displays, etc., are perceived as qualities of the store.

f. Store Clientel - the image of other shoppers represents the class appeal of the store.

A third purpose of this study, then, was to determine the relative importance of these evaluative criteria, and more importantly to offer contradictory evidence to the low ranking of price.

³Ibid., pp. 454-455.
CHAPTER II

PROJECT DESIGN

The Malmstrom Air Force Base Exchange may face a different consumer image than local retail outlets. The null hypothesis chosen for the purposes of this analysis, however, is that the Malmstrom Air Force Base Exchange (BX) faces the same consumer image as local retail outlets.

**Hypothesis**

The Survey

The data for this survey were gathered using a written questionnaire employing a six-point semantic differential scale (see Appendix 1). The semantic differential was selected as a measuring device because of its basic simplicity. Both the questionnaire and the analysis are less expensive and time consuming than other methods such as the Q Sort, Likert scale, Thurstone scale, and cumulative scale. The semantic differential does not sacrifice effectiveness at the expense of simplicity.

The semantic differential, developed by Osgood, Suci, and Tannenbaum,\(^1\) has been widely used in marketing research for determining consumer images. The selection of the number of cues (six-point in this case) is dependent on the type of research being performed and the accuracy required for determining significance. The six-point scale was

selected because it has enough cues to assume interval quality data, yet it does not have so many that it confuses or irritates the respondent.

The intent of the survey was to measure consumer images toward shopping in general (Question 4) and toward shopping at the BX (Question 5). The test of the hypothesis would then be a comparison of these images. The last four factors in Question 6 were used for control purposes, as was the advertising factor in Question 5. This simple control was used to void responses that circled the same end scale cues for opposite factors, for example, strongly agreeing with the statements that the BX has too many and too few product lines. Similarly, responses selecting advertising as the most important factor for shopping at the BX were voided, except as indicated above.

Demographic data were obtained in Questions 1 - 3. These data were necessary in order to break the sample into subgroups for further analysis.

The Sample

The population under consideration included all military personnel assigned to Malmstrom Air Force Base. At the time the survey was accomplished this population consisted of 5600 individuals, 970 of whom were officers and 4630 of whom were enlisted.

The sample was obtained by distributing questionnaires at twenty locations on the same day. The questionnaires were filled out immediately so assistance could be rendered if necessary and the control questions could be monitored. The presence of responses in the upper levels of the advertising factor under Question 5 represent individuals who shopped only at the BX when encouraged by word of mouth advertising.
The survey yielded 155 usable, completed questionnaires. This represented 2.77 percent of the total population, 6.19 percent of the officers and 2.05 percent of the enlisted personnel.
CHAPTER III

METHODS OF ANALYSIS

The initial step in the analysis of the data was determination of the frequency distributions. The data from Questions 4 and 5 were logged for all categories. These distributions are presented in table form (Appendix II) and graphic form (Appendix III).

Relying on an assumption of normality, parametric methods of analysis such as the "t test" could be applied to determine the significance of the hypothesis. However, the application of the "t test" to non-normal data yields biased and unreliable results. The Chi-square test for normality allowed the assumption of normality by statistically testing for "goodness of fit" to be foregone.

The null hypothesis for the Chi-square test is that the samples are normally distributed. A value of Chi-square falling outside of the 95 percent confidence intervals would indicate rejection of this null hypothesis. The Chi-square test, however, is not conclusive. Therefore, further tests were applied to the data. Significant differences obtained with the Chi-square test may indicate a skewed distribution. Further tests are applied to determine additional properties of the skewness. The test for skewness determines the extent and direction of skewness. The test for kurtosis determines the nature of the skewness. An example of the application of these tests to sample data is given in Table 1. The large value of Chi-square (8.823) falls well outside the 95 percent
confidence interval. Assuming that the sample was drawn from a normal population, this value would be exceeded only 3.4 percent of the time. The Chi-square value represents the amount that the sample distribution deviates from a perfectly normal distribution. This value indicates initial rejection of the null hypothesis which assumes normality. The test for skewness ($g_1$) verifies positive skewness through the large ratio $g_1/S.D.g_1$. The test for kurtosis ($g_2$) indicates a distribution with a flatter top than the normal distribution.

</table>

\[
m_2 = \frac{(x-\bar{x})^2}{\bar{f}} = \frac{385.91}{154} = 2.51 \quad \frac{m_2}{\bar{m}_2} = \frac{m}{\bar{m}} = 0.92 \\
m_3 = \frac{(x-\bar{x})^3}{\bar{f}} = \frac{837.37}{154} = 5.44 \quad S.D.g_1 = \sqrt{\frac{6}{154}} = 0.197 \\
m_4 = \frac{(x-\bar{x})^4}{\bar{f}} = \frac{1978.19}{154} = 12.85 \quad \frac{m_3}{\bar{m}_3} = \frac{m}{\bar{m}} = 0.92 \\
S.D.g_2 = \sqrt{\frac{24}{154}} = 0.395
\]
The result of this test is a rejection of the assumption of normality. In addition, the negative value of $g_2$ rejects the "t" distribution and other distributions derived from the normal distribution.

With the rejection of normality, the standard parametric methods of analysis could not be applied with any degree of reliability. While non-parametric methods do not lend themselves to sophisticated computations, they do enable one to test for significant differences without introducing unnecessary bias.

Of the several non-parametric tests available, the Wilcoxon signed rank test was selected for this analysis because it attaches importance to the magnitude of differences rather than merely accounting for the number of differences. This test is a non-parametric approximate of the "t" test. While the "t" test analyzes differences between means, the signed rank test is an analysis of the differences between medians.

An example of the signed rank test is given in Table 2. The differences between each response to Questions 4 and 5 are determined using Question 4 as the base point. The differences are then ranked, with the lowest rank (zero differences are not counted) being assigned to the smallest absolute difference. When differences are tied, each pair is assigned the average rank. When all differences are ranked, the sign of the difference is restored to the rank. The positive and negative ranks are then summed separately, yielding two rank sums. The smaller of these rank sums ($T$) is then used in the analysis to determine an approximate Z score with a correction factor for the discrete population ($-1/2$).

TOTAL 38.0 97.0

T (smaller rank sum) = 38

\[ Z = \left(1\mu - T_1 - 1/2\right)/\sigma \text{ where } \mu = n(n+1)/4 \text{ and } \sigma = (2n+1)/6 \]

\[ Z = (68-38-1/2)/19.3 = 1.528 \text{ since 1.528 is less than 1.96 the null hypothesis is not rejected at the 0.05 level of significance.} \]

Applying the 95 percent significance level, the Z score to be used for comparison with the result of the test is 1.96. Computed values greater than 1.96 indicate rejection of the null hypothesis. These values do not indicate acceptance of the hypothesis outright, but they do attach.
great reliability to the probability of correctness in accepting the hypothesis. The 95 percent significance level simply states that in 95 out of 100 samples the obtained values will be less than 1.96.

The results of the Wilcoxon signed rank test are given in Appendix IV. Where tables were used to determine significance (sixteen pairs or less) the approximate Z score is replaced by S, for significant, and I, for insignificant. For the example given in Table 2 the table indicates that for sixteen pairs, a T of twenty-nine or less is required for significance.
CHAPTER IV

RESULTS

The null hypothesis was rejected. The hypothesis is accepted at the 0.05 level of significance. The Malmstrom Air Force Base Exchange does face a different consumer image than local retail stores.

A factor by factor analysis yields more specific results:

Location. Only two major categories (OFFICER and MARRIED) indicate rejection of the null hypothesis. In both cases location was a more important factor in selecting a retail store than in shopping at the BX. Review of the medians (Appendix IV) for all categories supported the direction of this difference. Subjectively, it would seem that location would be a very important factor on the BX side. The fact that the population was always in contact with the BX could be one reason for the difference. Another reason could be a trade-off with the price factor.

Parking. All major categories (except SINGLE and ENLISTED) rejected the null hypothesis. Once again, this was a more important factor for retail shopping than for BX shopping.

Product Lines. Four major categories rejected the null hypothesis (TOTAL, OFFICER, SINGLE, and ON BASE). This factor was also more important for retail shopping.

Variety in Product Lines. All major categories rejected the null hypothesis. Again, this factor was more important in selecting a retail store.
Price. Only the OFFICER category rejected the null hypothesis. A review of the medians quickly showed why. In all cases, this was the most important factor for both retail and BX shopping. There was a difference in favor of the BX, but it was very small. This finding is contradictory to the findings of Rich and Portis\(^1\) and intuitively rejects their conclusion.

Advertising. All major categories rejected the null hypothesis. All categories report this was more important for retail shopping. This finding is consistent with the fact that the BX cannot advertise in the normal sense. The inclusion of several responses on the top end of the scale for Question 5 are the result of these respondents reporting word of mouth advertising as a very important factor in shopping at the BX. Several responses were not included due to the control factor of the question.

Appearance. All major categories except OFF BASE rejected the null hypothesis. Again, the difference was in favor of retail shopping.

Store Personnel. Four major categories (TOTAL, OFFICER, MARRIED, and OFF BASE) rejected the null hypothesis. This factor, too, was more important for retail shopping. Question 6 from the questionnaire is being submitted to the BX for further analysis of this factor.

Services Offered. TOTAL, OFFICER, MARRIED, SINGLE, and ON BASE rejected the null hypothesis. Again the findings indicate more importance for retail shopping.

The relative rankings of the evaluative criteria for both retail and BX shopping are shown in Table 3. These rankings were obtained using

\(^1\)Engel, Consumer Behavior, p. 452.
the median as the determinant of importance. (It should be noted that the same relative rankings were obtained using the mean.) The significance of these rankings are reflected in the magnitude of the medians. It is on the basis of these magnitudinal differences that the null hypothesis is rejected.

These same rankings are obtained using the means for the TOTAL category, except that no ties are noted.
CHAPTER V

CONCLUSIONS

Several conclusions can be drawn from the results of this study. The difference in consumer image is one of magnitude, unless there are other important factors of store selection that have not been reported. The reasons for this difference could be several, however, two possibilities stand out. First, the responses to Question 5 of the survey could be a means of showing general dissatisfaction with the BX. The importance of this factor has a carry-over effect on the importance of the other factors. The second conclusion was that the population is readily aware of the offerings of the BX. People do not have to rely on any evaluations other than price since they know what is available. On the basis of the data obtained by this survey, acceptance of either one of these conclusions cannot be made with any objective reliability.

Limitations

The success of this study can be judged by the extent in which it accomplished the three major purposes as set forward in the preface. To summarize, it identified which areas of marketing mix need improvement, it established the relative importance of the evaluative factors, and it indicated a possible general dissatisfaction with the BX.

The inconclusive evidence on this final factor is due to the limited amount of information available from the questionnaire. The
inclusion of more questions of the good-bad and agree-disagree variety would probably have remedied this problem.

The major limitation of this study was the limited population. Waiving the restrictions of time and money, the population could be extended to include wives and dependents. Since wives generally do most of the shopping, though not necessarily most of the buying, this would be a logical extension. The exclusion of wives could be partly responsible for the high ranking of PRICE revealed by the survey. To a man, shopping normally implies looking. Since the questionnaire did not offer a definition of shopping, the contradiction to Rich and Portis cannot be viewed as completely significant.

Also without the time and money restrictions, the sample could become a completely stratified random sample. A computer listing of Social Security Numbers, for example, could be obtained and random number selection used in mailing questionnaires.

Another major limitation was the limited definition of the BX. It is very difficult to visualize the BX as just one store (as directed in the questionnaire). The inclusion of all facilities and services would require many more categories to identify peculiarities in certain areas, i.e., determine any differences in consumer image among the BX facilities.

Correcting these limitations would undoubtedly lead to more significant research. However, this significance must be weighed against the additional costs and time involved. In light of this, the only real limitation of this study was the questionnaire.
APPENDIX I

The Questionnaire

This survey is being conducted to gather information which can be used by the Base Exchange to determine areas in which the BX can improve its services to you, the military family of MAFB. Your patience in answering the questions will be greatly appreciated.

DEFINITIONS

The BX, as defined in this survey, is limited to the Malmstrom Main Exchange only, NOT the Four Seasons and Outdoor Store.

"Product lines" are the different types of products carried, i.e., men's clothing, women's clothing, jewelry, uniforms and accessories.

"Variety within product lines" is the availability of different price ranges among similar products, i.e., men's pants ranging from $5 to $30.

DIRECTIONS

When answering Questions 4, 5, and 6, use the following guidelines. If you feel the concept is very closely related to one end of the scale or the other, circle either (1) or (6). If you feel it is closely related, circle either (2) or (5). If you feel it is only slightly related, circle either (3) or (4). DO NOT MARK BETWEEN THE NUMBERS.
