Cladistically modeling Oldowan assemblages: Preliminary insights and issues
Corey L. Johnson
University of Montana, Department of Anthropology

Introduction
This paper explores the evolutionary relationship of Oldowan assemblages from East Africa, North Africa, and the West Asia using cluster and cladistic analyses, and presents current issues with conducting such analyses. Cladistical techniques are useful for modeling cultural evolutionary relationships and can be used to understand evolutionary histories and patterns of change within the archaeological and historical record. The Lower Paleolithic (~3.3-0.6 Ma) archaeological record provides important information regarding the evolution of hominin behavior, landscape use, migration patterns, sensory-motor capabilities and cognitive complexity. In this respect the Oldowan technical system of the Lower Paleolithic (2.6-1.8) is an important and relatively unexplored topic for phylogenetic analysis and can be helpful in reconciling the ongoing debate of whether the Oldowan represents a technological stasis in early hominin culture or whether there is evidence for gradual evolution during the Oldowan leading up to the appearance of the Acheulean technological industry. One of the greatest obstacles currently facing phylogenetically testing the evolutionary relationships of Oldowan lithic assemblages is an inconsistency in typological and analytical practices in measuring the variability within and between lithic artifacts and assemblages.

Methods and Materials
The Oldowan site localities Gona (OGS-7/6)11, Lokalalei-2C (LA-2C)12, Olduvai Gorge (FLK, KJS)13, Koobi Fora (FKJ, Sahnouni)14, Melka Kunture (Garba_IVE-F)15, Fige (FJ-1), Ain Janech (Ain_Han)16, Bizat Pabaila (BRAT5/BR1996)17 and Dam trimming (Upper_B1)18 were selected as taxa for the cluster and cladistic analyses due to their similar sample size (N=1000), association with faunal remains (Type C)19, and having primary context. A more complete analysis would include more assemblages. Lemkwi 3 (LE-3)20 was used as an outgroup to establish directionality of the cladogram as it is the least derived and most ancestral archaeological assemblage known to date.

Lithic data for each assemblage was obtained from the literature and coded using the presence/absence of a selection of de la Torre's21 idealized schemes of hand core reduction (Fig. 1), mean flake type based on Toth's22 flake types (Fig. 2), and evidence for bipolar flaking. These character traits were selected because of their technological nature, and their ability to be correlated with the several different Oldowan typological frameworks used for these different sites in the literature. They are preliminary character traits and do not represent the full range of technological variability recorded in the Oldowan.

The resulting binary matrix of character traits of the different Oldowan assemblage taxa (Table 1) was entered into the paleontological statistics program PAST23. A Euclidean Neighbor Joining (rooted on the outgroup) and hierarchical cluster analysis (UPGMA), and a parsimony analysis using the Branch and Bound algorithm (found to be most parsimonious tree) under Fitch optimization (characters are reversible and unordered, meaning that all changes have equal cost) were then run.

Summary and Conclusion
This paper analyses Oldowan assemblages using augmented data from the literature to produce a cladogram which could be used as a testable hypothesis of phylogenetic relationships within and between the different sites. The results of the cladistics analysis suggest a branching pattern of hortilaturation during the Oldowan and begs the interpretation of whether a punctuated evolutionary model of Oldowan technology representing a "stasis" during the Early Lower Paleolithic is shown, or that a gradual evolution is taking place at the different sites through time. However, without synthesized holistic and qualitative Oldowan assemblage data that can be correlated between sites accurately a meaningful cladistic analysis could not be performed, and the results of these analyses must be viewed as preliminary.

Future research should continue to work towards holistically modeling the environmental and behavioral factors which shape Oldowan assemblages and toward a universally held Oldowan lithic techno-typological system. This will require collaborative efforts to construct such a system and the revisiting of past collections and reanalyzing lithic materials in order to build a synthetic body of information. The system and information should be made accessible in an independent manner to allow for the testing of Oldowan models beyond those within a single technological context.

Discussion
Previous attempts at phylogenetically modeling the Oldowan technological industry have been few-to-none to the author’s knowledge. This may be in part due to the several debates currently surrounding the evolutionary nature of the Oldowan, and a lack of a "synthetic and reductive method of Oldowan analysis"28. Several other factors which affect Oldowan hominin lithic assemblage organization must also be taken into account in order to phylogenetically model the evolutionary relationships of assemblage sized taxa such as: raw material quality29, paleoenvironmental context30, landscape use31, distance from raw material source32, site use33, and raw material size34. These other contextual issues are not modeled in this analysis, and are necessary to holistically test phylogenetic relationships of Oldowan assemblages. Future analyses will need to take these factors into account in order to accurately reflect evolutionary relationships of these and other assemblages.

Acknowledgments
This paper is dedicated to Anna Preti, Randall Schoen, and Ignacio de la Torre for their valuable comments on the submitted abstract for this poster, and Corey Ogden and Anna Preti for their comments on the poster itself.
